

AIT's Data centre infrastructure management (DCIM) solution manages British Airways' 6 Data Centres

British Airways (BA) is a full service global airline, with an extensive route network flying from its Heathrow and Gatwick hubs as well as to and from many regional and international airports. Following its merger with Iberia to form the IAG group, British Airways has become the world's third largest airline.

AIT was approached by BA for advice on upgrading and extending the use of the airlines data centre infrastructure management tools it uses to allocate space, control work flow and aid capacity planning across its two sites near BA's Waterside HQ at Heathrow.

The Challenge

BA was an early adopter of data centre infrastructure management (DCIM) software and wanted to extend its use with an easy to use flexible solution that could make server allocation faster and provide instant reporting and real time dashboards of power and cooling capacity.

The Solution

After consulting with BA on their needs and considering several options including the upgrading of the incumbent DCIM software, AIT recommended implementing a new DCIM solution; Raritan's dcTrack. This met the airlines criteria at a fraction of the cost of upgrading the incumbent software. AIT was able to save time and costs by updating and then transferring data from BA's existing DCIM software and importing it into dcTrack which minimised the requirement for physical auditing of the data halls.

"...AIT provided the expertise and man power to audit and upload data, incorporate our modifications, and support the team,"
Keith Bott, Service Manager,
British Airways.

BA has a very large IT infrastructure with over 500 data cabinets spread across 6 halls in two different sites near its Heathrow Waterside HQ.

AIT project managed the implementation and mapped all the server and IT assets as well as the network and power cabling connections in BA's data halls into dcTrack to provide an easy to use solution that displays real-time information as well as asset and capacity reporting. AIT worked closely with Raritan to incorporate several enhancement requests for British Airways, which were subsequently released into the general release of dcTrack.

The Result

British Airways is now using dcTrack across its data centre infrastructure to manage server, power and network connectivity. Any planned changes are first put into dcTrack which instantly identifies which racks have cooling, power and space capacity using its extensive library and interactive floor plan. All approved moves and changes are made using the work order system within dcTrack to ensure physical assets are connected in the right rack.

A key element to the successful installation was the ability of AIT to quickly amend and import existing data and physically audit assets and infrastructure. This together with the willingness of Raritan to develop product enhancements to suit customer needs and BA's understanding of the importance of managing a dynamic data centre environment made for a successful project.

“The new DCIM software allows us to quickly allocate space for new servers, manage power and network connectivity, issue work orders and provide capacity planning across all British Airways data centres,” Keith Bott, Service Manager, British Airways. “AIT provided the expertise and man power to audit and upload data, incorporate our modifications, and support the team during initial role out, to give us a leading edge DCIM solution that meets our exact needs.”
